

Intro JavaScript

1. Sum 3 Numbers

Write a JS function that takes three numbers as input and outputs their sum.

The **input** comes as array of string elements that need to be parsed as numbers.

The **output** should be printed to the console.

Examples

Input	Output
['2', '3', '4']	9

Input	Output
['1.5', '1.5', '-1']	2

2. Sum And VAT

Write a JS function that sums a variable number of prices and calculates their VAT (Value Add Tax, 20%).

The **input** comes as array of string elements that need to be parsed as numbers. The number of elements will be different every time.

The **output** should be printed to the console on a new line for every entry.

Input	Output
['1.20', '2.60', '3.50']	sum = 7.3 VAT = 1.46 total = 8.76

Input	Output
['3.12', '5', '18', '19.24', '1953.2262', '0.001564', '1.1445']	sum = 1999.732264 VAT = 399.94645280000003 total = 2399.6787168

3. Letter Occurrences In String

Write a JS function that counts how many times a specific letter occurs in a given string.

The **input** comes as array of string elements. The first element is the string to check and the second element is the letter to count.

The **output** should be returned as a result of your function.

Input	Output
['hello', 'l']	2

Input	Output
['panther', 'n']	1

4. Filter By Age

Write a JS function that stores the name and age of two persons in objects and then filters them by minimum age.

The **input** comes as array of string elements. The first element is the minimum age. The second and third elements are the name and age of the first person and the fourth and fifth elements – the name and age of the second person. The three age parameters need to be parsed as numbers.

The **output** should be printed to the console.

Input	Output
['12', 'John', '15', 'Alfred', '9']	{ name: 'John', age: 15 }

5. String Of Numbers 1...N

Write a JS function that read a number **n** as input and prints all numbers from 1 to **n**, concatenated as a single string.

The **input** comes as array of one string element that needs to be parsed as a number.

The **output** should be returned as a result of your function.

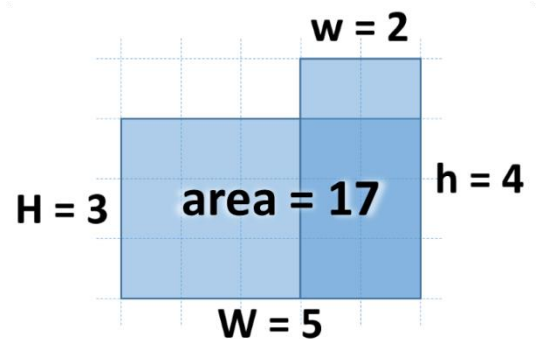

Input	Output
['11']	'1234567891011'

6. Figure Area

Write a JS function that calculates the area of the figure on the right by given values for **w**, **h**, **W** and **H**. The lower right corner is always common for the two rectangles.

The **input** comes as array of string elements that need to be parsed as numbers.

The **output** should be returned as a result of your function.

Examples

Input	Output	Input	Output
['2', '4', '5', '3']	17	['13', '2', '5', '8']	56

7. Next Day

Write a JS function that calculates the date of the next day by given year, month and day.

The **input** comes as array of three string elements that need to be parsed as numbers. The first element is the year, the second is the month and the third is the day.

The **output** should be returned as a result of your function.

Examples

Input	Output
['2016', '9', '30']	2016-10-1

8. Distance between Points

Write a JS function that calculates the distance between two points by given x and y coordinates. Use objects to store the two points.

The **input** comes as array of four string elements in the format **[x1, y1, x2, y2]** that need to be parsed as numbers. Each pair of elements are the coordinates of a point in 2D space.

The **output** should be returned as a result of your function.

Examples

Input	Output
['2', '4', '5', '0']	5

Input	Output
['2.34', '15.66', '-13.55', '-2.9985']	24.50778901186315
