

Django Lab 4

We have learned a lot about setting up Models-Templates-Views. Now its time for you to get some practice!

1. Start a new project or reuse the one you already have. Up to you.
2. Add a new model called User. It should have these fields:
 - **First Name**
 - **Last Name**
 - **Email**
1. Make sure you make the migrations!
2. Create a script that will populate your database with fake Users.
3. Confirm the populating through the Admin interface.
4. Create a view for your website for the domain extension /users
5. This /users page will be an HTML list of the user names and emails.
6. You will use template tags to generate this content from the User model.
7. Remember to change your urls.py files to deal with the changes to the /users extension!

Example:

index page:

/users page:
